Name:

Plant Transport: Option 1

Plants are incredible organisms! They can make all their own food from the simple inputs of sunlight, carbon dioxide, and water. This biological wizardry is accomplished through the magic of photosynthesis. This process can be summarized by the equation below.

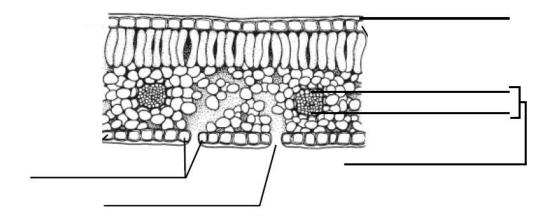

$6 \text{ CO}_2 + 6 \text{ H}_2\text{O} + \text{light energy} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6 \text{ O}_2$

This means that plants are able to harness the energy of the sun to turn CO2 from the air into the carbon-based molecules of life — carbohydrates, proteins, lipids, and nucleic acids.

Plants capture the sun's light within their green leaves. Inside a leaf's cells are green organelles — chloroplasts — which do all this hard work of producing the food that feeds the plant... and, in fact, the whole rest of the world, too! To do this job best, leaves have evolved a specific structures.

The epidermis is the outer layer of cells that acts like a protective "skin" for the leaf. Covering the epidermis is a waxy coating, called the **cuticle**, which stops evaporation of water from the leaves thereby helping plants conserve water. In the lower epidermis are openings called **stomata** surrounded by two cells called **guard cells**. The stomata act like the lungs of the plant in that they allow gas exchange — letting CO2 into the inner plant tissues for photosynthesis and then allowing O2 out as a waste product of photosynthesis. The mesophyll is the main inner leaf tissue making up the blade of the leaf. Most of the photosynthesis of the plant takes place in the mesophyll. The **vascular tissue** functions like the circulatory system of the plant. The **xylem** carries water from the roots to the leaves and to the other upper parts of the plant. The **phloem** carries the sugars produced during photosynthesis in the chloroplasts of the leaves to any place else in the plant that needs the food. Xylem and phloem are found in vascular bundles in the veins of the leaf.

1. Below is a diagram of a cross section through a leaf. <u>LABEL</u> the **bolded** structures discussed above.

2. Below is a cross section of a Lilac leaf under a micro scope. Identify the structures.

3.	What are the 3 functions of stomata?
4.	Why are most of the stomates on the bottom of the leaf?
5.	Why are the epidermis layers of the leaf coated in a waxy cuticle?
6.	What is the function of the xylem?
7.	What is the function of the phloem?
8.	Describe how the functions of the xylem and phloem specifically relate to photosynthesis. A. xylem
	B. phloem
9.	Where in the leaf does photosynthesis take place?
	Where in the leaf does photosynthesis take place? What is the function of guard cells?
10.	
10.11.12.	What is the function of guard cells? When do stomata need to be open? Under what conditions would guard cells close the stomates?
10.11.12.13.	What is the function of guard cells? When do stomata need to be open?
